

## DET10C - April 27, 2018

Item # DET10C was discontinued on April 27, 2018. For informational purposes, this is a copy of the website content at that time and is valid only for the stated product.

### HIGH-SPEED PHOTODETECTORS

- ▶ Monitor CW or Fast Pulsed Lasers
- ▶ Detectors for Wavelengths from 150 to 2600 nm
- ▶ Integrate with Cage or Lens Tube Systems

#### Application Idea

**DET36A2**  
Biased Si Detector

**DET10D2**  
Biased InGaAs Detector

DET Series Detector Attached to a 30 mm Cage System Using the Included SM1 Coupler and an SM1T2 Adapter (See the *Housing Features* Tab for Details)

[Hide Overview](#)

#### OVERVIEW

##### Features

- 11 Models Cover the 150 nm to 2.6  $\mu\text{m}$  Wavelength Range
- Rise Times as Fast as 1 ns
- Compact Housing for Measurements in Tight Spaces
- SM05 Lens Tube, SM1 Lens Tube, Cage System, and  $\text{\O}1/2$ " Post Compatible
- Internal A23 12 V Bias Battery Included (Optional Power Adapter and Power Supply Available Below)
- Can be Fiber Coupled Using Our Internally and Externally SM1-Threaded Fiber Adapters

Click to Enlarge  
Each detector has an internal SM05 and external SM1 thread and comes with an attached SM1T1 Internal SM1 Adapter and SM1RR Retaining Ring.

##### Operating Circuit Diagram

Click to Enlarge  
The detectors are reverse biased to produce a linear response with applied input light.

Thorlabs' Biased Photodetectors are available in eleven models that cover the wavelength range from the UV to the mid-IR (150 nm to 2.6  $\mu\text{m}$ ). The slim housing allows the optical detector to slip into tight setups. Each model comes complete with a fast PIN photodiode and an internal bias battery packaged in a rugged aluminum housing. Our biased photodetectors are compatible with our benchtop photodiode amplifier and PMT transimpedance amplifier.

With a wide bandwidth DC-coupled output, these detectors are ideal for monitoring fast pulsed lasers as well as DC optical sources. The direct photodiode anode current is provided on a side panel BNC. This output is easily converted to a positive voltage using a terminating resistor. When looking at high-speed signals, Thorlabs recommends using a 50  $\Omega$  load resistor. For lower bandwidth applications, our variable terminator or fixed stub-style terminators quickly adjusts the measured voltage. The detectors below do not have amplifiers or built-in gain, which generally allows them to operate at higher speeds than our PDA series of amplified photodetectors; for applications that require gain or switchable filters, a PDA amplified photodetector may be more suitable.

All connections and controls are located away from the light path, which simplifies integration of our detectors in enclosed spaces. Every detector has internal SM05 (0.535"-40) threading and external SM1 (1.035"-40) threading. Each DET housing includes a detachable  $\text{\O}1$ " Optic Mount (SM1T1) that allows for  $\text{\O}1$ " optical components, such as optical filters and lenses, to be mounted along the optical axis. Each DET detector can also be mounted in a

Click to Enlarge

DET10D2

cage system, lens tube system, or on a  $\varnothing 1/2$ " optical post. Except for the DET10C and DET20C, each unit's housing features two universal taps that accept both 8-32 and M4. The housing for the DET10C and DET20C features two 8-32 tapped holes (M4 for /M models). For more information about the location of these mounting points and mounting these units, please see the *Housing Features* and *Mounting Options* tabs.

Click to Enlarge  
PDA200C Benchtop Photodiode Amplifier Connected to  
a DET10A2 Photodetector Using a BNC Cable

Each detector is reverse-biased by an A23 12 VDC battery incorporated into the housing. The housing also includes a red button (pictured to the left) which, when held down, applies the battery's voltage across the external load. For a high-Z load, this will output the battery's voltage over BNC, providing an easy way to determine if the battery should be replaced without removing it from the housing. An in-line current-limiting resistor prevents fast battery drainage if the battery is tested while connected to a 50  $\Omega$  load. Please note that due to slight physical variations of the positive terminal from manufacturer to manufacturer, Thorlabs only recommends using an Energizer<sup>®</sup> battery in our DET series of photodetectors. A battery was chosen for the reverse bias because it provides an extremely low noise source of power. If the finite lifetime of a battery is not acceptable, the battery can be replaced by a DET2B power adapter bundle. Extra batteries and the DET2B are available for purchase below.

Please note that inhomogeneities at the edges of the active area of the detector can generate unwanted capacitance and resistance effects that distort the time-domain response of the photodiode output. Thorlabs therefore recommends that the incident light on the photodiode is well centered on the active area. The SM1 (1.035"-40) threading on the housing is ideally suited for mounting a  $\varnothing 1$ " focusing lens or pinhole in front of the detector element.

Thorlabs also offers high-speed free-space detectors and high-speed fiber-coupled detectors for wavelengths between 400 - 1700 nm.

HOUSING FEATURES

**DET Series Housing Features**

Thorlabs' high-speed detectors feature a slim design. Each housing features internal SM05 (0.535"-40) threading and external SM1 (1.035"-40) threading. All detectors include an SM1T1 internally SM1-threaded adapter and an SM1RR retaining ring. Most SM1-threaded fiber adapters are compatible with these detectors.

Threaded holes on the housings of the detectors allow the units to be mounted in a horizontal or vertical orientation, which gives the user the option to route the power and BNC cables from above or alongside the beam path. Except for the DET10C and DET20C, each detector features two universally threaded holes compatible with both 8-32 and M4 threads and has the back panel engraved with the responsivity curve of the photodiode for convenience. The DET10C and DET20C have a housing that features two 8-32 threaded holes, while its metric counterpart has two M4 threaded holes (see the table below). For more information on mounting these units, please see the *Mounting Options* tab.

50  $\Omega$  Recommended Termination. For max output, please see detector drawings below.

[Hide Battery Lifetime](#)

## BATTERY LIFETIME

### Battery Lifetime

When using a battery-operated photodetector, it is important to understand the battery's lifetime and how this affects the operation of the detector. As a current output device, the output current of the photodetector is directly proportional to the amount of incident light on the detector. Most users will convert this current to a voltage by using a terminating load resistor. The resistance value is approximately equal to the circuit gain. For very high speed detectors, such as the DET08 series, it is very important to use a 50  $\Omega$  terminating resistor to match the impedance of standard coaxial cables to reduce cable reflections and improve overall signal performance and integrity. Most high-bandwidth scopes come equipped with this termination.

The battery usage lifetime directly correlates to the current used by the detector. Most battery manufacturers provide a battery lifetime in terms of mAh (milliamp hours). For example, if a battery is rated for 190 mA hrs, it will reliably operate for 190 hr at a current draw of 1.0 mA. This battery will be used in the following example on how to determine battery lifetime based on usage.

For this example we have a 780 nm light source with an average 1 mW power is applied to a detector. The responsivity of a biased photodetector based on the response curve at this wavelength is 0.5 A/W. The photocurrent can be calculated as:

$$\begin{aligned} I_{current} &= 0.5 \text{ A/W} \times 1 \text{ mW} \\ &= 0.5 \text{ mA} \end{aligned}$$

Given the battery has a rated lifetime of 190 mA hr, the battery will last:

$$\begin{aligned} T &= \frac{190 \text{ mA hr}}{0.5 \text{ mA}} \\ &= 380 \text{ hr} \end{aligned}$$

or 16 days of continuous use. By reducing the average incident power of the light to 10  $\mu$ W, the same battery would last for about 4 years when used continuously. When using the recommended 50  $\Omega$  terminating load, the 0.5 mA photocurrent will be converted into a voltage of:

$$\begin{aligned} V &= I \times R \\ &= 0.5 \text{ mA} \times 50 \Omega \\ &= 25 \text{ mV} \end{aligned}$$

If the incident power level is reduced to 40  $\mu$ W, the output voltage becomes 1 mV. For some measurement devices this signal level may be too low and a compromise between battery life and measurement accuracy will need to be made.

When using a battery-powered, biased photodetector, it is desirable to use as low a light intensity as is possible, keeping in mind the minimum voltage levels required. It is also important to remember that a battery will not immediately cease producing a current as it nears the end of its lifetime. Instead, the voltage of the battery will drop, and the electric potential being applied to the photodiode will decrease. This in turn will increase the response time of the detector and lower its bandwidth. As a result, it is important to make sure the battery has sufficient voltage (as given in the *Troubleshooting* chapter of the detector's manual) for the detector to operate within its specified parameters. The voltage can be checked with a multimeter.

Another suggestion to increase the battery lifetime is to remove, or power down the light source illuminating the sensor. Without the light source, the photodetector will continue to draw current proportional to the photodetector's dark current, but this current will be significantly smaller.

For applications where a DET series photodetector is continuously illuminated with a relatively high-power light source, or if having to change the battery is not acceptable, we offer the DET2B power adapter bundle, which includes the power adapter and power supply (sold below). The drawback to this option is the noise in the line voltage will add to the noise in the output signal and could cause more measurement uncertainty.

[Hide Mounting Options](#)

## MOUNTING OPTIONS

The DET series biased photodiode detector housing is compatible with our line of TR series  $\text{\O}1/2"$  posts, lens tubes, and cage systems. Because of the flexibility, the best method for mounting the housing in a given optical setup is not always obvious. The pictures and text in this tab will discuss some of the common mounting solutions. As always, our technical support staff is available for individual consultation.

		
<p>Picture of a DET series biased photodiode detector as it will look when unpackaged.</p>	<p>Picture of a DET series biased photodiode detector with the included SM1T1 and its retaining ring removed from the front of the housing.</p>	<p>A close up picture of the front of a DET series biased photodiode detector with the SM1T1 removed. The external SM1 and internal SM05 threading on the detector housing can be seen in this image.</p>

### TR Series Post ( $\text{\O}1/2"$ Posts) System

The DET housing can be mounted vertically or horizontally on a  $\text{\O}1/2"$  Post using the universally threaded holes for both 8-32 and M4 threads on all detectors, except the DET10C and DET20C. These two detectors have 8-32 (M4) threaded holes.

	
<p>DET series detector mounted horizontally on a TR series post. In this configuration, the on/off switch is easily accessible from the top.</p>	<p>DET series detector mounted vertically on a TR series post.</p>

### Lens Tube System

Each DET housing includes a detachable  $\text{\O}1"$  Optic Mount (SM1T1) that allows for  $\text{\O}1"$  ( $\text{\O}25.4$  mm) optical components, such as optical filters and lenses, to be mounted in front of the photosensitive region. The maximum thickness of an optic that can be mounted in the SM1T1 is  $0.1"$  ( $2.8$  mm). For thicker  $\text{\O}1"$  ( $\text{\O}25.4$  mm) optics or for  $\text{\O}0.5"$  ( $\text{\O}12.7$  mm) optics of any thickness, remove the SM1T1 from the front of the detector and place an SM1 or SM05 series lens tube (must be purchased separately), respectively, on the front of the detector.

The SM1 and SM05 threading on the DET biased photodiode detector housing make it compatible with our SM lens tube system and accessories. Two particularly useful accessories include the SM threaded irises and the SM compatible IR and visible alignment tools. Also available are fiber optic adapters for use with connectorized fibers.

## Cage System

The simplest method for attaching the DET photodetector housing to a cage plate is to remove the SM1T1 that is attached to the front of the PDA and use the external SM1 threads. A cage plate, such as the CP02 30 mm cage plate, can be directly attached to the SM1 threads. Then the retaining ring, included with the SM1T1, can be threaded using a spanner wrench into the CP02 to ensure the cage plate is tightened to the desired location and square with the photodetector housing.

This method for attaching the DET biased photodiode has the benefit of not needing an adapter piece and it allows the photodiode to be as close as possible to the cage plate, which can be important in setups where the light is divergent. On a side note, Thorlabs sells the SM05PD and SM1PD series of photodiodes that can be threaded into a cage plate so that the diode is flush with the front surface of the cage plate; however, the photodiode is unbiased.

For more freedom in choosing the orientation of the DET biased photodiode detector housing when attaching it, an SM1T2 lens tube coupler can be purchased. In this configuration the SM1T1 is left on the detector and the SM1T2 is threaded into it. The exposed external SM1 threading is now deep enough to secure the biased photodiode detector to a CP02 cage plate in any orientation and lock it into place using one of the two locking rings on the ST1T2.

Although not pictured here, the DET detector housing can be connected to a 16 mm cage system by purchasing a SM05T2. It can be used to connect the DET detector housing to a SP02 cage plate.

## Application

The image below shows a Michelson Interferometer built entirely from parts available from Thorlabs. This application demonstrates the ease with which an optical system can be constructed using our lens tube, TR series post, and cage systems.

The table contains a part list for the Michelson Interferometer for use in the visible range.

Item #	Quantity	Description	Item #	Quantity	Description
KC1	1	Mirror Mount	SM1V05	1	Ø1" Adjustable Length Lens Tube
BB1-E03	2	Broadband Dielectric Laser Mirrors	SM1D12	1	SM1 Threaded Lens Tube Iris
ER4	8	Cage Rods, 4" Long	CP08FP	1	30 mm Cage Plate for FiberPorts
ER6	4	Cage Rods, 6" Long	SM1Z		Cage System Z-Axis Translation Mount
CCM1-BS014	1	Mounted Beamsplitting Cube	SM1L30	1	Ø1" Lens Tube, 3" in Length
DET36A2	1	Biased Photodiode Detector	PAF2-2B	1	FiberPort

[Hide Photodiode Tutorial](#)

## PHOTODIODE TUTORIAL

### Photodiode Tutorial

#### Theory of Operation

A junction photodiode is an intrinsic device that behaves similarly to an ordinary signal diode, but it generates a photocurrent when light is absorbed in the depleted region of the junction semiconductor. A photodiode is a fast, highly linear device that exhibits high quantum efficiency based upon the application and may be used in a variety of different applications.

It is necessary to be able to correctly determine the level of the output current to expect and the responsivity based upon the incident light. Depicted in Figure 1 is a junction photodiode model with basic discrete components to help visualize the main characteristics and gain a better understanding of the operation of Thorlabs' photodiodes.

$$I_{OUT} = I_{DARK} + I_{PD}$$

Figure 1: Photodiode Model

## Photodiode Terminology

### Responsivity

The responsivity of a photodiode can be defined as a ratio of generated photocurrent ( $I_{PD}$ ) to the incident light power ( $P$ ) at a given wavelength:

$$R(\lambda) = \frac{I_{PD}}{P}$$

### Modes of Operation (Photoconductive vs. Photovoltaic)

A photodiode can be operated in one of two modes: photoconductive (reverse bias) or photovoltaic (zero-bias). Mode selection depends upon the application's speed requirements and the amount of tolerable dark current (leakage current).

#### Photoconductive

In photoconductive mode, an external reverse bias is applied, which is the basis for our DET series detectors. The current measured through the circuit indicates illumination of the device; the measured output current is linearly proportional to the input optical power. Applying a reverse bias increases the width of the depletion junction producing an increased responsivity with a decrease in junction capacitance and produces a very linear response. Operating under these conditions does tend to produce a larger dark current, but this can be limited based upon the photodiode material. (Note: Our DET detectors are reverse biased and cannot be operated under a forward bias.)

#### Photovoltaic

In photovoltaic mode the photodiode is zero biased. The flow of current out of the device is restricted and a voltage builds up. This mode of operation exploits the photovoltaic effect, which is the basis for solar cells. The amount of dark current is kept at a minimum when operating in photovoltaic mode.

#### Dark Current

Dark current is leakage current that flows when a bias voltage is applied to a photodiode. When operating in a photoconductive mode, there tends to be a higher dark current that varies directly with temperature. Dark current approximately doubles for every 10 °C increase in temperature, and shunt resistance tends to double for every 6 °C rise. Of course, applying a higher bias will decrease the junction capacitance but will increase the amount of dark current present.

The dark current present is also affected by the photodiode material and the size of the active area. Silicon devices generally produce low dark current compared to germanium devices which have high dark currents. The table below lists several photodiode materials and their relative dark currents, speeds, sensitivity, and costs.

Material	Dark Current	Speed	Spectral Range	Cost
Silicon (Si)	Low	High Speed	Visible to NIR	Low
Germanium (Ge)	High	Low Speed	NIR	Low
Gallium Phosphide (GaP)	Low	High Speed	UV to Visible	Moderate
Indium Gallium Arsenide (InGaAs)	Low	High Speed	NIR	Moderate
Indium Arsenide Antimonide (InAsSb)	High	Low Speed	NIR to MIR	High
Extended Range Indium Gallium Arsenide (InGaAs)	High	High Speed	NIR	High
Mercury Cadmium Telluride (MCT, HgCdTe)	High	Low Speed	NIR to MIR	High

#### Junction Capacitance

Junction capacitance ( $C_j$ ) is an important property of a photodiode as this can have a profound impact on the photodiode's bandwidth and response. It should

be noted that larger diode areas encompass a greater junction volume with increased charge capacity. In a reverse bias application, the depletion width of the junction is increased, thus effectively reducing the junction capacitance and increasing the response speed.

#### Bandwidth and Response

A load resistor will react with the photodetector junction capacitance to limit the bandwidth. For best frequency response, a 50  $\Omega$  terminator should be used in conjunction with a 50  $\Omega$  coaxial cable. The bandwidth ( $f_{BW}$ ) and the rise time response ( $t_r$ ) can be approximated using the junction capacitance ( $C_j$ ) and the load resistance ( $R_{LOAD}$ ):

$$f_{BW} = 1 / (2 * \pi * R_{LOAD} * C_j)$$
$$t_r = 0.35 / f_{BW}$$

#### Noise Equivalent Power

The noise equivalent power (NEP) is the generated RMS signal voltage generated when the signal to noise ratio is equal to one. This is useful, as the NEP determines the ability of the detector to detect low level light. In general, the NEP increases with the active area of the detector and is given by the following equation:

$$NEP = \frac{\text{Incident Energy} * \text{Area}}{\frac{S}{N} * \sqrt{\Delta f}}$$

Here, S/N is the Signal to Noise Ratio,  $\Delta f$  is the Noise Bandwidth, and Incident Energy has units of  $W/cm^2$ . For more information on NEP, please see Thorlabs' Noise Equivalent Power White Paper.

#### Terminating Resistance

A load resistance is used to convert the generated photocurrent into a voltage ( $V_{OUT}$ ) for viewing on an oscilloscope:

$$V_{OUT} = I_{OUT} * R_{LOAD}$$

Depending on the type of the photodiode, load resistance can affect the response speed. For maximum bandwidth, we recommend using a 50  $\Omega$  coaxial cable with a 50  $\Omega$  terminating resistor at the opposite end of the cable. This will minimize ringing by matching the cable with its characteristic impedance. If bandwidth is not important, you may increase the amount of voltage for a given light level by increasing  $R_{LOAD}$ . In an unmatched termination, the length of the coaxial cable can have a profound impact on the response, so it is recommended to keep the cable as short as possible.

#### Shunt Resistance

Shunt resistance represents the resistance of the zero-biased photodiode junction. An ideal photodiode will have an infinite shunt resistance, but actual values may range from the order of ten  $\Omega$  to thousands of  $M\Omega$  and is dependent on the photodiode material. For example, and InGaAs detector has a shunt resistance on the order of 10  $M\Omega$  while a Ge detector is in the  $k\Omega$  range. This can significantly impact the noise current on the photodiode. For most applications, however, the high resistance produces little effect and can be ignored.

#### Series Resistance

Series resistance is the resistance of the semiconductor material, and this low resistance can generally be ignored. The series resistance arises from the contacts and the wire bonds of the photodiode and is used to mainly determine the linearity of the photodiode under zero bias conditions.

## Common Operating Circuits

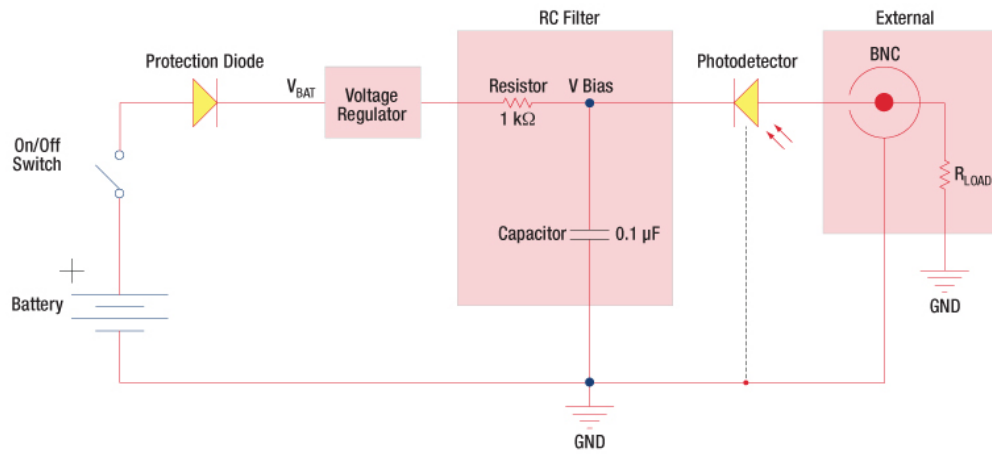

Figure 2: Reverse-Biased Circuit (DET Series Detectors)

The DET series detectors are modeled with the circuit depicted above. The detector is reverse biased to produce a linear response to the applied input light. The amount of photocurrent generated is based upon the incident light and wavelength and can be viewed on an oscilloscope by attaching a load resistance on the output. The function of the RC filter is to filter any high-frequency noise from the input supply that may contribute to a noisy output.

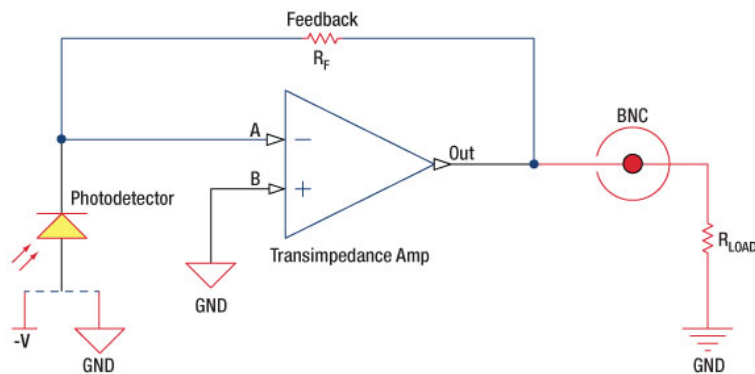

Figure 3: Amplified Detector Circuit

One can also use a photodiode with an amplifier for the purpose of achieving high gain. The user can choose whether to operate in Photovoltaic or Photoconductive modes. There are a few benefits of choosing this active circuit:

- Photovoltaic mode: The circuit is held at zero volts across the photodiode, since point A is held at the same potential as point B by the operational amplifier. This eliminates the possibility of dark current.
- Photoconductive mode: The photodiode is reverse biased, thus improving the bandwidth while lowering the junction capacitance. The gain of the detector is dependent on the feedback element ( $R_f$ ). The bandwidth of the detector can be calculated using the following:

$$f(-3dB) = \sqrt{\frac{GBP}{4\pi * R_f * C_D}}$$

where GBP is the amplifier gain bandwidth product and  $C_D$  is the sum of the junction capacitance and amplifier capacitance.

### Effects of Chopping Frequency

The photoconductor signal will remain constant up to the time constant response limit. Many detectors, including PbS, PbSe, HgCdTe (MCT), and InAsSb, have a typical  $1/f$  noise spectrum (i.e., the noise decreases as chopping frequency increases), which has a profound impact on the time constant at lower frequencies.

The detector will exhibit lower responsivity at lower chopping frequencies. Frequency response and detectivity are maximized for

$$f_c = \frac{1}{2\pi\tau_r}$$

[Hide Lab Facts](#)

## LAB FACTS

### Dark Current as a Function of Temperature or Reverse-Bias Voltage

Measurements of dark current as a function of temperature and dark current as a function of reverse-bias voltage were acquired for several packaged detectors. As is described in the following section, dark current is a relatively small electrical current that flows in p-n junction photodetectors when no light is incident on the detector. For certain applications, it may be necessary to account for the change in dark current as temperature fluctuates and/or as the reverse-bias voltage changes. As a consequence of a battery's supplied voltage decreasing as it drains, the relationship between the reverse-bias voltage and the dark current level may be of particular interest if a battery is used to reverse-bias voltage the photodiode.

One set of measurements were taken for silicon (Si), germanium (Ge), and indium gallium arsenide (InGaAs) reverse-biased photodiodes over temperatures from 10 °C to 50 °C, and another set of measurements were taken for the same detectors while they were held at 24 °C and the reverse-bias voltage varied from 0 to 10 V. Please click the "More [+]" labels in the following expandable tables to read about the experiments and our measurements.

### Current-Voltage Characteristics of p-n Junction Photodiodes

The characteristic current-voltage relationship of p-n junction photodiodes includes a forward-biased and a reverse-biased voltage regime. Operation of p-n junction photodiodes occurs in the reverse-biased voltage regime, in which a potential difference is applied across the diode to resist the flow of current. A convenient feature of some packaged photodiodes is that a battery inserted into the package can supply the reverse-bias voltage. Ideally, if no light is incident on a reverse-biased photodiode, no current flows.

Under real-world conditions, random processes in the semiconductor material of the photodiode always generate current carriers (electrons and holes) that produce current. These current generation processes are not driven by the photogeneration of electrons and holes. Instead, they are largely driven by the thermal energy contained in the semiconductor material.[1] This dark current is generally small, but it is present when the photodiode is reverse biased and not illuminated. Dark current magnitudes vary for photodiodes of different material compositions; the efficiencies of the thermal generation processes depend on the type and crystal quality of the semiconductor used in the detector's sensing head. The magnitude of the dark current can be expected to increase as the temperature of the photodiode increases and as the reverse-bias voltage applied to the photodiode increases.

It is important to note that if the reverse bias voltage is increased beyond a certain threshold, the photodiode will suffer reverse breakdown, in which the magnitude of the current increases exponentially and permanent damage to the diode is likely. For this reason, many of the Thorlabs DET packages include a voltage regulator to prevent the bias voltage from reaching breakdown.

When a photodiode is illuminated, the current generated by the incident light adds to the dark current. The carriers in the photocurrent are generated by the energy contained in the photons of the incident light. Above a certain illumination threshold intensity, the magnitude of the photocurrent exceeds the magnitude of the dark current. When the photocurrent is larger than the dark current, the magnitude of the photocurrent can be calculated by measuring the total current and then subtracting the contribution of the dark current. When the photocurrent is smaller than the noise on the dark current, the photocurrent is undetectable. Because of this, it is desirable to minimize the levels of dark current in photodiodes.

[Hide Replacement Batteries for Photodetectors](#)

### Replacement Batteries for Photodetectors

- ▶ **A23:** For Currently Shipping DET Photodetectors
- ▶ **SBP12:** For Discontinued SV2-FC and SIR5-FC Fiber-Coupled Photodetectors
- ▶ **T505:** For Discontinued DET1-SI and DET2-SI Detectors

#### A23 and T505 Alkaline Batteries

The A23 and T505 are replacement alkaline batteries for Thorlabs' currently shipping and discontinued DET photodetectors. For cases where the finite lifetime of a battery is not acceptable, we also offer an AC power adapter; please see below for more information. Information on expected battery lifetime is in the *Battery Lifetime* tab above.

#### SBP12 Battery Pack

The SBP12 is a 12 V replacement alkaline battery pack for our SV2-FC and SIR5-FC fiber-coupled photodetectors. It completely replaces the 20 V battery that was originally used (Item # SBP20), which we can no longer offer due to shipping regulations. Our testing shows that a 12 V bias provides performance similar to a 20 V bias, and the performance is within the detectors' stated specifications.

As shown by the photo to the right, the SBP12 consists of an A23 battery in a newly designed housing. You may already own this housing if you purchased your SV2-FC or SIR5-FC in or after October 2013, or if you have already purchased an SBP12. If you do own this housing, then it is necessary to purchase only the A23 battery.

Customers who own an SV2-FC or SIR5-FC detector purchased before October 2013 will need to bend two pins to ensure that the SBP12 battery pack makes electrical contact. The procedure is illustrated in the spec sheet of the battery, which can be downloaded [here](#).

Part Number	Description	Price	Availability
A23	Replacement 12 V Alkaline Battery for DET Series (Except DET1-SI and DET2-SI)	\$5.03	Today
SBP12	Replacement 12 V Alkaline Battery Pack for SV2-FC or SIR5-FC	\$85.94	Today
T505	Replacement 22.5 V Alkaline Battery for DET1-SI and DET2-SI	\$17.14	Today

### DET Power Adapter

Click to Enlarge  
The DET2B bundle can replace the battery in the DET series

- ▶ **DET2A:** Power Adapter for DET Series Detectors
- ▶ **LDS12B:** ±12 VDC Power Supply
- ▶ **DET2B:** Includes Both the DET2A and LDS12B

[DET2B Installation Procedure](#)

#### DET2A Power Adapter

The DET2A is a power adapter for our DET series detectors. This power adapter will directly replace the A23 battery and spring-loaded cap to allow the detector to run directly from our LDS12B power supply (sold separately). The DET2A is also compatible with the PDA-C-

detectors, as shown with the DET50B2.

72 power supply cable for custom connections. Note that when connecting the DET2A and the PDA-C-72 to power DET series detectors, only the brown (+12 V) and black (GND) pins are needed.

### LDS12B Power Supply

The LDS12B is a  $\pm 12$  VDC regulated power supply, which incorporates a current limit, enabling short circuit and overload protection; an on/off switch with an LED indicator; and a switchable AC input voltage (100, 120, or 230 VAC). A region-specific power cord is shipped with the LDS12B power supply based on your location.

### DET2B Power Adapter Bundle

The DET2B power adapter bundle includes both the DET2A power adapter and the LDS12B power supply. This power adapter bundle can be used to replace the battery in our DET series detectors. To use the DET2B, simply replace the battery and spring-loaded cap with the included DET2A adapter, and then insert the three pin plug from the LDS12B power supply into the adapter. This procedure is depicted in the animation to the above right.

Part Number	Description	Price	Availability
DET2A	NEW! DET Power Adapter	\$39.50	Today
LDS12B	NEW! $\pm 12$ VDC Regulated Linear Power Supply, 6 W, 100/120/230 VAC	\$80.33	Today
DET2B	NEW! DET Power Adapter & Power Supply Bundle	\$118.00	Today

[Hide Internally SM1-Threaded Fiber Adapters](#)

### Internally SM1-Threaded Fiber Adapters

These internally SM1-threaded (1.035"-40) adapters mate connectorized fiber to any of our externally SM1-threaded components, including our photodiode power sensors, our thermal power sensors, and our photodetectors. These adapters are compatible with the housing of the photodetectors on this page.

Item #	S120-SMA	S120-ST	S120-SC	S120-LC

S120-ST	ST/PC Fiber Adapter Cap with Internal SM1 (1.035"-40) Thread	\$39.78	Today
S120-SC	SC/PC Fiber Adapter Cap with Internal SM1 (1.035"-40) Thread	\$49.98	Today
S120-LC	LC/PC Fiber Adapter Cap with Internal SM1 (1.035"-40) Thread	\$49.98	Today

[Hide Externally SM1-Threaded Fiber Adapters](#)

### Externally SM1-Threaded Fiber Adapters

- ▶ Externally SM1-Threaded (1.035"-40) Disks with FC/PC, FC/APC, SMA, or ST/PC Receptacle
- ▶ Light-Tight When Used with SM1 Lens Tubes
- ▶ Compatible with Many of Our 30 mm Cage Plates and Photodetectors

Each disk has four dimples, two in the front surface and two in the back surface, that allow it to be tightened from either side with the SPW909 or SPW801 spanner wrench. The dimples do not go all the way through the disk so that the adapters can be used in light-tight applications when paired with SM1 lens tubes. Once the adapter is at the desired position, use an SM1RR retaining ring to secure it in place.

Item #	SM1FC	SM1FCA <sup>a</sup>	SM1SMA	SM1ST
Adapter Image (Click the Image to Enlarge)				
Connector Type	FC/PC	FC/APC	SMA	ST/PC
Threading	External SM1 (1.035"-40)			

a. Please note that the SM1FCA has a mechanical angle of only 4°, even though the standard angle for these connectors is 8°. There is a 4° angle of

deflection caused by the glass-air interface; when combined with the 4° mechanical angle, the output beam is aligned perpendicular to the adapter face.

Part Number	Description	Price	Availability
SM1FC	FC/PC Fiber Adapter Plate with External SM1 (1.035"-40) Thread	\$29.58	Today
SM1FCA	FC/APC Fiber Adapter Plate with External SM1 (1.035"-40) Thread	\$31.37	Today
SM1SMA	SMA Fiber Adapter Plate with External SM1 (1.035"-40) Thread	\$29.58	Today
SM1ST	ST/PC Fiber Adapter Plate with External SM1 (1.035"-40) Thread	\$28.42	Today
